# The Agentic Ops Build

**Submit:** GitHub repo + working URL + Loom (3–5 min) + a short decisions README

## The situation

A mid-market omnichannel retailer runs demand planning and replenishment in spreadsheets and a legacy ERP screen. A planner manually pulls sales, eyeballs trends, and places purchase suggestions every week. It’s slow, it’s wrong at the long tail, and the one planner who understands it is a single point of failure. Leadership wants “AI” but cannot articulate what good looks like.

This is an AI-led business operations problem — downstream ops that quietly shape the customer experience (stockouts, over-discounting, late replenishment). Your task is to reimagine the planner’s workflow as an agentic system and build a credible working prototype of it.

## What we want you to produce

- 1. A reimagined workflow.** Show the current human loop, then the agentic version: what the agent senses, decides, drafts, and escalates to a human. Be explicit about where the human stays in the loop and why.
- 2. A working agentic prototype.** Build a system that ingests sample sales/inventory data and produces replenishment or demand recommendations with reasoning a planner could trust. It should handle at least one realistic edge case (a demand spike, a supplier lead-time change, a long-tail SKU) visibly and well.
- 3. A trust & control layer.** How does a planner verify, override, or correct the agent? How does the system explain itself? Design and at least partially build this — it is the hard part, not an afterthought.
- 4. An honest limitations section.** Where would this fail in production at real data volume? What did you mock? What would you never ship as-is?

## Constraints & freedom

| Area    | Constraint                                                              |
|---------|-------------------------------------------------------------------------|
| LLM     | NA                                                                      |
| Data    | Synthesize realistic multi-week sales + inventory data (your structure) |
| Stack   | Any framework; deployability and a live URL matter                      |
| Agentic | Show genuine sense→decide→act→escalate logic, not a single prompt call  |

How we score Case 02

| Dimension          | What strong looks like                                                |
|--------------------|-----------------------------------------------------------------------|
| AI-native judgment | Agent design fits the real ops loop; AI used where it earns its place |
| Build depth        | Runs end to end on realistic data; handles an edge case visibly       |
| Product thinking   | Human-in-the-loop, trust, and override designed deliberately          |
| Articulation       | Decisions README and Loom make the reasoning legible and honest       |
